

Essential Characteristics

GE Receiving Tubes

Canadian General Electric Company Limited

May 1951

Scanned by VE6BPO January 2007.

ESSENTIAL CHARACTERISTICS—RECEIVING TYPES is especially prepared to provide the Service Technician with a single source of reference containing data on every tube apt to be found in any home receiver—AM, FM, or Television.

Data presented include those characteristics and ratings essential to fast, efficient, trouble-shooting. Basing diagrams for each type are shown on the page with the data.

The electronics engineer, amateur, and experimenter will also find this a valuable quick-reference for tubes currently in use.

Included in the present edition of this handbook are the many new receiving tubes recently announced for use in Television applications; a comprehensive coverage of subminiature tubes; and a new section listing the essential physical and electrical characteristics of Television Picture Tubes.

To aid in the proper evaluation of the information presented in this handbook, a section entitled "Interpretation of Ratings and Technical Data" has been included. Following this section is a chart of "Recommended Types" which will provide the Service Technician with a valuable guide to tubes apt to be found in the late-model receivers.

Requests for additional data on specific uses of individual types will receive prompt attention if addressed to:

INTERPRETATION OF RATINGS AND TECHNICAL DATA

I. MAXIMUM RATINGS

Unless otherwise specified, the maximum tube ratings in this manual have been prepared in accordance with the RTMA system of Design Center Maximums and should be interpreted as defined in paragraphs 1 and 2 given below.

1. Cathode

The heater or filament voltage is given as a normal value unless stated otherwise. This means that transformers or resistances in the heater or filament circuit should be designed to operate the heater or filament at rated value for full-load operating conditions under average supply-voltage conditions. A reasonable amount of leeway is incorporated in the cathode design so that moderate fluctuations of heater or filament voltage downward will not cause marked falling off in response; also, moderate voltage fluctuations upward will not reduce the life of the cathode to an unsatisfactory degree.

A. 1.4-volt Battery Tube Types

The filament power supply may be obtained from dry-cell batteries, from storage batteries, or from a power line. With dry-cell battery supply the filament may be connected either directly across a battery rated at a terminal potential of 1.5 volts, or in series with the filaments of similar tubes across a power supply consisting of dry cells in series. In either case, the voltage across each 1.4-volt section of filament should not exceed 1.6 volts. With power-line or storage-battery supply, the filament may be operated in series with the filaments of similar tubes. For such operation, design adjustments should be made so that, with tubes of rated characteristics, operating with all electrode voltages applied and on a normal line voltage of 117 volts or on a normal storage-battery voltage of 2.0 volts per cell (without a charger) or 2.2 volts per cell (with a charger), the voltage drop across each 1.4-volt section of filament will be maintained within a range of 1.25 to 1.4 volts with a nominal center of 1.3 volts. In order to meet the recommended conditions for operating filaments in series from dry-battery, storage batteries, or power-line sources it may be necessary to use shunting resistors across the individual 1.4-volt sections of filament.

B. 2.0-volt Battery Tube Types

The 2.0-volt line of tubes is designed to be operated with 2.0 volts across the filament. In all cases the operating voltage range should be maintained within the limits of 1.8 volts to 2.2 volts.

2. Positive Potential Electrodes

The power sources for the operation of radio equipment are subject to variations in their terminal potential. Consequently, the maximum ratings given in this manual have been established for certain Design Center Voltages which experience has shown to be representative. The Design Center Voltages to be used for the various power supplies together with other rating considerations are as given below.

A. A-C or D-C Power-line Service in U.S.A.

The design center voltage for this type of power supply is 117 volts. The maximum ratings of plate voltages, screen-supply voltages, dissipations, and rectifier output currents are design maximums and should not be exceeded in equipment operated at a line voltage of 117 volts.

B. Storage-battery Service

When storage-battery equipment is operated without a charger, it should be so designed that the published maximum values of plate voltages, screen-supply voltages, dissipations, and rectifier output currents are never exceeded for a terminal potential at the battery source of 2.0 volts per cell. When storage-battery equipment is operated with a charger it should be so designed that 90 per cent of the same values are never exceeded for a terminal potential at the battery source of 2.2 volts per cell.

C. B-Battery Service

The design center voltage for B-batteries is the normal voltage rating of the battery block, such as 45 volts, 90 volts, etc. Equipment should be so designed that under no condition of battery voltage will the plate voltages, the screen-supply voltages, or dissipations ever exceed the recommended respective maximum values shown in the data for each tube type by more than 10 per cent.

D. Other Considerations

a. Class A Amplifiers

The maximum plate dissipation occurs at the Zero-signal condition. The maximum screen dissipation usually occurs at the condition where the peak-input signal voltage is equal to the bias voltage.

b. Class B Amplifiers

The maximum plate dissipation theoretically occurs at approximately 63 per cent of the Maximum-signal condition, but practically may occur at any signal-voltage value.

c. Converters

The maximum plate dissipation occurs at the Zero-signal condition and the frequency at which the oscillator-developed bias is a minimum. The screen dissipation for any reasonable variation in signal voltage must never exceed the rated value by more than 10 per cent.

d. Screen Ratings

The maximum screen voltage rating may be exceeded provided that all the following conditions are satisfied:

1. At any operating condition the screen voltage does not exceed the maximum plate voltage rating.
2. At any operating condition the average screen dissipation does not exceed the maximum rating.
3. At the operating condition which results in maximum screen current, the screen voltage does not exceed the value required for maximum screen dissipation. This condition, however, may not represent the maximum dissipation condition.

3. Absolute Maximum Ratings

In some instances, the maximum ratings are specified as Absolute Maximum Ratings. The absolute maximum ratings represent the limiting values above which the serviceability of the tube may be impaired from the viewpoint of life and satisfactory performance. Therefore in order not to exceed these absolute ratings, the equipment designer has the responsibility of determining an average design value for each rating below the absolute value of that rating by an amount such that the absolute values will never be exceeded under any usual condition of supply-voltage variation, manufacturing variations (including components) in the equipment itself, or adjustment of controls.

II. TYPICAL OPERATING CONDITIONS

For many receiving tubes, the data show typical operating conditions in particular services. These typical operating values are given to show concisely some guiding information for the use of each type. They are not to be considered as ratings, because the tube can be used under any suitable conditions within its rating limitations.

III. GENERAL

1. Interelectrode Capacitances

- A. Unless otherwise noted, all capacitance values indicated in this manual are average values.
- B. Unless otherwise noted, all capacitance values indicated in this manual for glass tubes are measured with a close-fitting metal shield as standardized by RTMA.

2. Use of Pin No. 1 on Octal Types

Pin No. 1 on metal receiving tubes is usually connected to the outer shell of the tube. Certain glass tubes with octal bases have internal shields connected to this pin. In order to obtain correct operation of octal based tubes, Pin No. 1 should never be used as a terminal for any voltage or portion of the electrical circuit, but should be connected to ground whenever possible.

3. Use of GT/G Suffix

The use of the suffix GT/G on small glass receiving tubes has been eliminated and for this reason does not appear in this manual. Data on tubes which have been previously marked as GT/G types may be obtained by referring to the data under the GT listing (for example, characteristics of the 6J5-GT/G will be found under the 6J5-GT listing).

4. Rectifier Characteristics

Unless otherwise noted, all ratings and characteristics, presented for rectifier tubes apply to operation with a capacitor-input filter. In general, operation with a choke-input filter allows the use of a slightly higher RMS supply voltage.

5. Metal Types

Metal tube type designations are shown in boldface type on the following pages to facilitate the location of these types in the tabular material.

6. Miniature Types

The type designations of miniature tubes are shown in italics on the following pages for ease of location in the tabular material.

7. X-Ray Radiation from TV Picture Tubes

Cathode-ray tubes rated at anode voltages in excess of 16,000 volts may require x-ray radiation shielding to avert possible danger of personal injury from prolonged exposure at close range. The protective fore-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window is not in excess of 6.25 milliroentgens per hour the window will provide adequate protection.

RECOMMENDED TYPES

Filament	Tetradodes		Voltage Amplifiers		Pentodes	
	Single	Twin	With Diodes	Sharp Cutoff	Remote Cutoff	With Diodes
0 thru 2.8 volts	6AB4 <i>6C4</i>	6J6 <i>6SN7-GT</i>	6AV6 <i>6SQ7</i> <i>6T8</i>	6AU6 <i>6BC5</i> <i>6CB6</i>	IT4	<i>IT5</i>
5.0 thru 6.3 volts

+Special treatment of faceplate to reduce reflection.

♦ Reflective, metal-backed screen to increase light output.

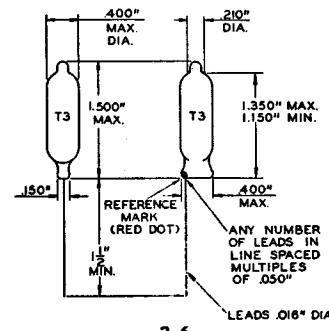

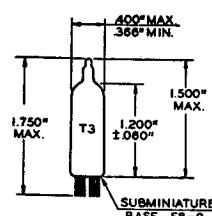

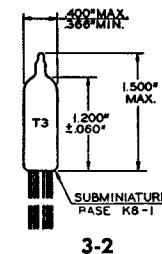

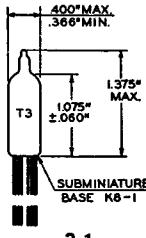

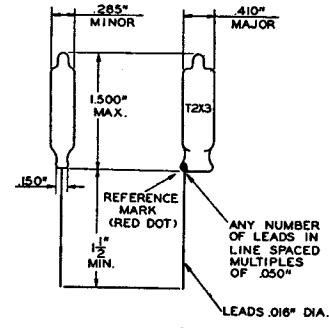

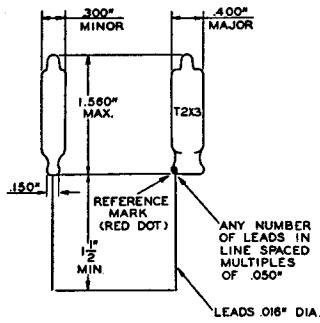

■ For visual extinction of undeflected focused spot.

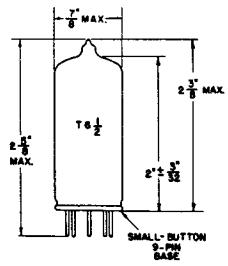

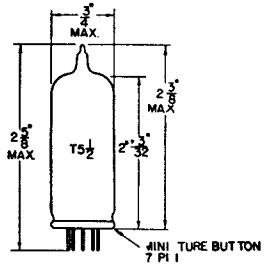

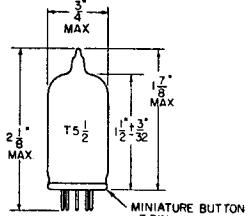

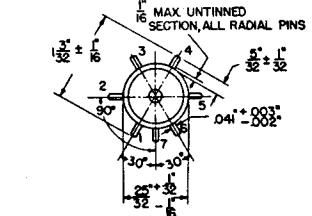

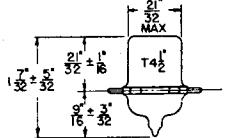

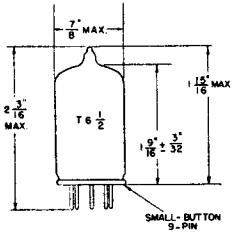

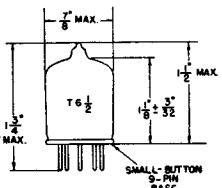

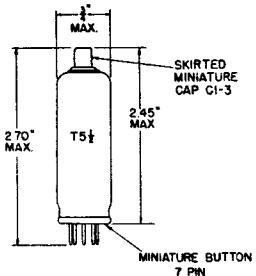

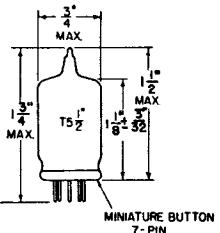

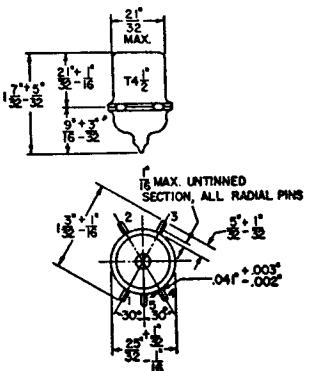

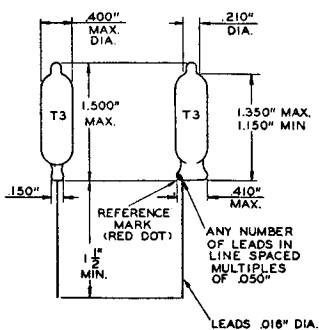

‡Plate-to-plate.
